5. Inheritance

🟪 Keyword `extends` is used to create inherit relationship between class
🟪 For inherit relationship child class can use parent class properties

```javascript
class Father {
    //Properties
    first_name='Jhon'
    last_name='Dee'
    //method
    getName() {
        return (`The name of the person is ${this.first_name} ${this.last_name}`)
    }
}

class Son extends Father{

}

const SonObj = new Son();
console.log(SonObj.getName());
```

🟪 Call parent class function and properties in child class

```javascript
class Father {
    //Properties
    first_name = 'Jhon';
    last_name = 'Dee';
    //method
    getName() {
        return `The name of the person is ${this.first_name} ${this.last_name}`;
    }
}

class Son extends Father {
    getFirstName() {
        return this.getName();
    }
}

const son = new Son();
console.log(son.getFirstName());
```
